# Introduction

---

ITOPF's annual Oil Tanker Spill Statistics publication presents data on accidental spills of oil from tankers. This includes incidents involving both persistent and non-persistent oil from tankers, except those resulting from acts of war. It provides information on oil spills recorded in the last year and an overview of the number and size of oil tanker spills since 1970.

Data is held on over 10,000 oil spills from tankers, including combined carriers, FPSOs and barges. This includes the location and cause of the incident, the vessel involved, the type of oil spilt and the amount of oil spilt. Spills are categorised by size, ie small (<7 tonnes or 50 bbls), medium (7-700 tonnes or 50-5000 bbls) or large (>700 tonnes or 50,000 bbls), although the actual amount spilt is also recorded.

Information is gathered from shipping and other specialist publications, as well as from vessel owners, their insurers and ITOPF's own experience at incidents. Historically, information from published sources related mostly to large spills, often resulting from collisions, groundings, structural damage, fire or explosions. Nevertheless, in recent decades reporting of smaller spills has improved.

It should be noted that the estimate of the amount of oil spilt in an incident includes all oil lost to the environment, including that which burnt or remained in

a sunken vessel. There is considerable annual variation in both the number of oil spills and the amount lost. While we strive to maintain precise records for all spill information, we cannot guarantee that the information taken from the shipping press and other sources is complete or accurate. The number of incidents and volumes of oil spilt are recorded based on the most up to date information available. Occasionally, data is received after publication and, in this case, adjustment to previous entries may be made. Consequently, the figures in the following tables, and any averages derived from them, should be viewed with a degree of caution.

It is also important to note that accidental spills from tankers account for only a small percentage of the oil that enters the oceans each year. Pipeline spills, oil industry activities, petroleum usage (including oil spills from non-tankers and 'run-off' from roads and other land-based sources), as well as natural seepage, all contribute towards annual inputs. Therefore, ITOPF's report shows only part of the picture relating to global input of oil into the marine environment.

**For further information on ITOPF's tanker spill statistics, please contact Naa Sackeyfio, Information Data Analyst ([naasackeyfio@itopf.org](mailto:naasackeyfio@itopf.org)). We regret that it is not possible to provide direct access to our database or to release the names of individual tanker incidents.**

# Tanker Spills Recorded in 2021

Six oil spills over 7 tonnes were recorded from tanker incidents in 2021. This is a slight increase on 2020, but on a par with the average for the 2010s and a dramatic reduction from the numbers reported in earlier decades.

Only one of the six incidents in 2021 resulted in a spill greater than 700 tonnes (classified as a 'large' spill). This occurred in Asia in April and involved heavy crude oil. The five other incidents (classified as 'medium' spills) involved crude, slurry and non-persistent oils. Two of these incidents occurred in Africa, two in Asia and one in North America.

The total volume of oil lost to the environment from tanker spills in 2021 was approximately 10,000 tonnes, the majority of which was spilt in the one large incident. This figure is higher than the previous two years but remains a fraction of the 1.7 billion tonnes<sup>1</sup> of oil that is transported by sea each year.

Despite some annual fluctuations, the number and volume of oil spills from tankers have plummeted since ITOPF's records began half a century ago and are largely stabilising at a low level. This reduction has been driven by positive change from the shipping industry, supported by governments, and their ongoing commitment to exploring and investing in ways to improve maritime safety and environmental protection.

# Major Oil Spills in History

A summary of the 20 largest oil spills that have occurred since the TORREY CANYON in 1967 is given in Table 1 and their geographical locations are shown in Figure 1. It is of note that 19 of the 20 largest spills recorded occurred before the year 2000. SANCHI, the most recent addition to the top 20, is the only major spill of non-persistent oil featured here and it

resulted in significantly lower environmental impacts compared to some crude oil spills listed. A number of these incidents, despite their large size, necessitated little or no response as the oil was spilt some distance offshore and did not impact coastlines. PRESTIGE, EXXON VALDEZ and HEBEI SPIRIT are included for comparison.

| Position | Shipname                  | Year | Location   | Spill size (tonnes) |
|----------|---------------------------|------|--|---------------------|
| 1        | ATLANTIC EMPRESS          | 1979 | Off Tobago, West Indies                          | 287,000             |
| 2        | ABT SUMMER                | 1991 | 700 nautical miles off Angola                    | 260,000             |

# Number of Oil Spills

The number of oil spills from tankers has decreased significantly over the last few decades. Spills in excess of 7 tonnes have reduced by over 90% since 1970.

| 1970s          | Year        | 7-700<br>Tonnes | >700<br>Tonnes |
|----------------|-------------|-----------------|----------------|
|                | 1970        | 7               | 29             |

\* Following the publication of the previous statistical report, notification was received of an incident in Africa that occurred late last year. Consequently, the figures for 2020 have been revised.

Table 2: Annual number of oil spills (>7 tonnes) from tankers

# Quantities of Oil Spilt

From 1970 to 2021, approximately 5.87 million tonnes of oil was lost as a result of tanker incidents globally. However, there has been a significant reduction in the volume of oil spilt through the decades. Currently, the volume of oil lost in accidents is a tiny fraction of the volume that is delivered safely to its destination each year.

| 1970s        | Year             | Quantity (Tonnes) |
|--------------|------------------|-------------------|
|              | 1970             | 383,000           |

\* Figures in table are annual estimates for spills >7 tonnes, rounded to the nearest thousand.

Table 3: Annual quantity of oil spilt from tanker incidents

# Global Oil Spill Trend

Over the past half a century, statistics for the frequency of spills greater than 7 tonnes from tankers have shown a marked downward trend. As illustrated in Figure 2 below, the average number of

spills per year in the 1970s was about 79 and decreased by over 90 percent to 6 in the 2010s. So far this decade, the annual average number of oil spills is 5, one less than the average recorded last decade.

Figure 2: Number of medium (7-700 tonnes) and large (>700 tonnes) tanker spills from 1970-2021

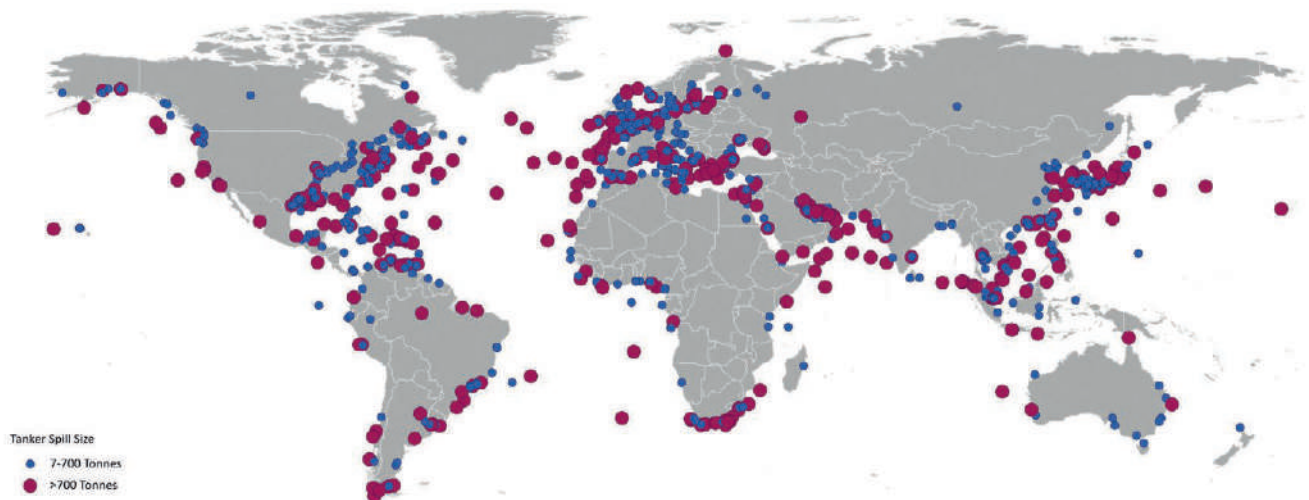

Figure 3: Map of tanker spills (>7 tonnes) from 1970-2021 (All rights reserved © ITOPF)

# Spill Frequency Analysis

Data on spills of 7 tonnes and over has been analysed to identify trends and reveal patterns in reported oil spills. Unfortunately, data on small spills (<7 tonnes), which forms over 80% of spills recorded since 1970, has been excluded. Information on this category of spills is often incomplete thus reliable reporting is difficult to achieve.

The number of large (>700 tonnes) and medium

(7-700 tonnes) have decreased significantly over the past 52 years as shown in Figure 4. The annual average number of spills recorded this decade is less than a tenth of the average recorded in the decade 1970 -1979, for both spill size classes. It is, however, interesting to note that the progressive reduction in the number of spills is significant when data is analysed per decade. Data recorded from 1970 to 2021 illustrates fluctuations in the yearly values within a decade (Figure 2).

\* Only two years of data available for the 2020s

Figure 4: Number of medium (7-700 tonnes) and large (>700 tonnes) tanker spills, 1970-2021

Figure 5: Medium (7-700 tonnes) and large (>700 tonnes) tanker spills as a percentage of those recorded per decade, 1970-2021

A quarter of all spills recorded over 7 tonnes are large.

More than half of these (52%) occurred in the 1970s (Figure 5).

# Spill Quantity Analysis

In terms of the volume of oil spill, the figures for a particular year may be severely distorted by a single

large incident, as illustrated below.

Figure 6: Quantities of oil spill 7 tonnes and over (rounded to nearest thousand) from tanker incidents, 1970-2021

Figure 7 below also demonstrates the influence of a few very large spills on the estimated quantities of oil spill. The following can be seen for recent decades:

- In the 1990s there were 358 spills of 7 tonnes and over, resulting in 1,134,000 tonnes of oil lost; 73% of this amount was spilled in just 10 incidents.

- In the 2000s there were 181 spills of 7 tonnes and over, resulting in 196,000 tonnes of oil lost; 75% of this amount was spilled in just 10 incidents.
- In the 2010s there were 63 spills of 7 tonnes and over, resulting in 164,000 tonnes of oil lost; 91% of this amount was spilled in just 10 incidents. One incident was responsible for about 70% of the quantity of oil spill.

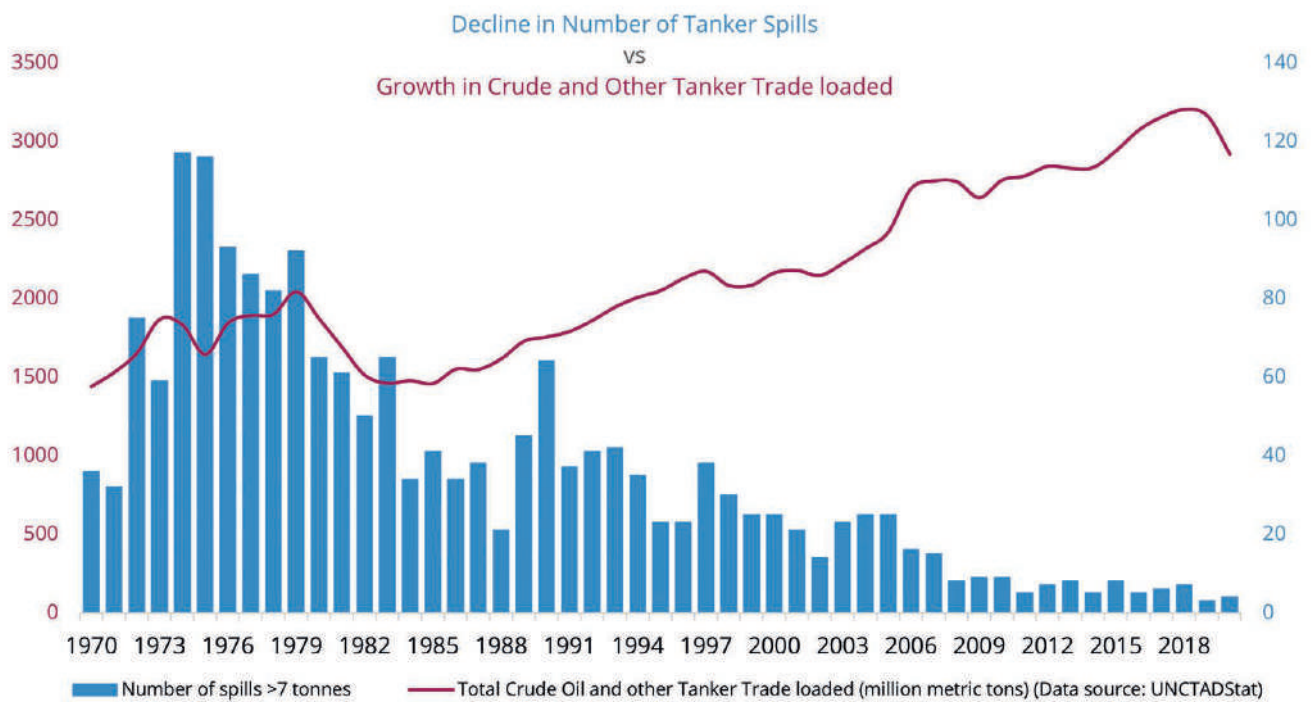

\* 2020s excluded. Only two years of data available.

Figure 7: Tanker spills 7 tonnes and over per decade showing the influence of a relatively small number of comparatively large spills on the overall figure

# Tanker Spills versus Seaborne Oil Trade

International seaborne oil trade has grown steadily since the 1970s, except for a fall in the early 1980s during the worldwide economic recession (Figure 8). A fall can also be seen for 2020 but the full effect of Covid-19 is still unclear at this stage. Conversely, the

frequency of oil spills has continued to decline despite an overall increase in oil trading over the period. Presently, over 99.99% of oil transported by sea arrives safely at its destination.

\* UNCTADStat information is not yet available for 2021

Figure 8: Decline in number of tanker spills vs growth in crude and other tanker trade loaded, 1970-2020

# Causes of Spills

The causes and circumstances of oil spills are varied, and their analyses provide valuable insights for managing risk. This information is, however, difficult to obtain as data is sometimes inconsistent or not available, particularly for small spills.

For this analysis, the primary causes of oil spills greater than 7 tonnes have been grouped into Allisions/

Collisions, Groundings, Hull Failures, Equipment Failures, Fires and Explosions, Others and Unknown. Events such as heavy weather damage and human error have been categorised as "Other" and spills where the relevant information is not available have been designated as Unknown and are reported but excluded from the analysis. Figure 9, below, provides an overview of the causes by size of spill.

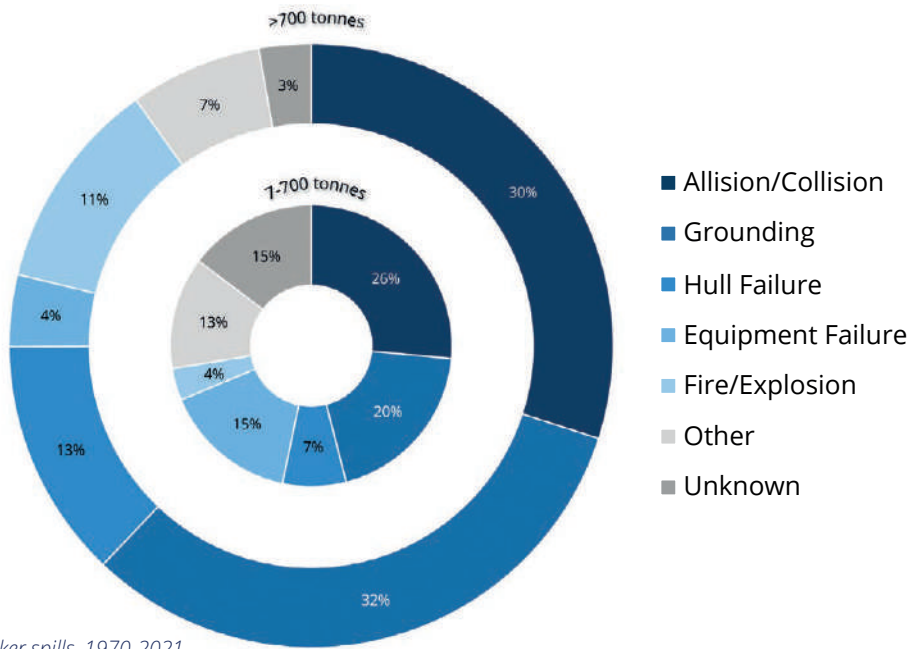

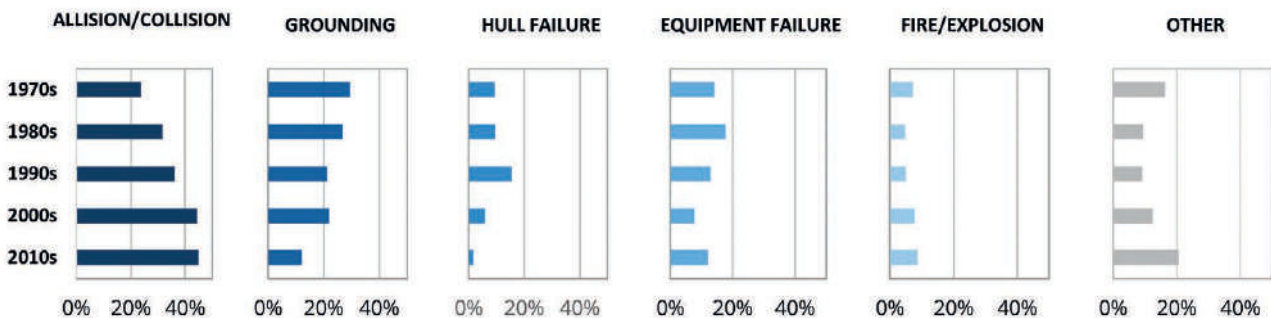

Figure 9: Causes of tanker spills, 1970-2021

## The most frequent causes of oil spills (>7 tonnes) from tankers are Allisions/Collisions and Groundings

Most oil spills (>7 tonnes) recorded between 1970 and 2021 were caused by Allisions/Collisions and Groundings. From Figure 10 below, it is evident that whilst the overall number of spills has reduced over the decades, the proportion of those that arise from Allisions/Collisions has increased and those

due to Groundings have decreased. Figure 10 also demonstrates a decrease in the proportion of spills caused by Hull Failure, with a significant drop after the 1990s. The outlook for this decade is uncertain, with only two years of data recorded.

\*2020s excluded. Only two years of data available.

Figure 10: Causes of tanker spills per decade, 1970-2019

It can also be seen from Figure 11 that less than 10% of spills (>7 tonnes) are caused by fires and explosions. Interestingly, the quantity of oil lost as a result of Fire/

Explosion is comparable to the quantity spilt from Groundings and Allisions/Collisions, each responsible for about 26% of the total quantity of oil spilt since 1970.

Figure 11: Number of tanker spills and quantity spilt per cause, 1970-2021

# Vessel Operation at Time of Spill

In the following analysis, the operation that the vessel was undertaking at the time of the incident is explored.

Reporting of large spills (>700 tonnes) tends to provide more information and greater accuracy than smaller

spills. Vessel operations have therefore been grouped into Loading/Discharging, Bunkering, At Anchor (Inland/Restricted waters), At Anchor (Open water), Underway (Inland/Restricted waters), Underway (Open water), Other Operations and Unknown Operations.

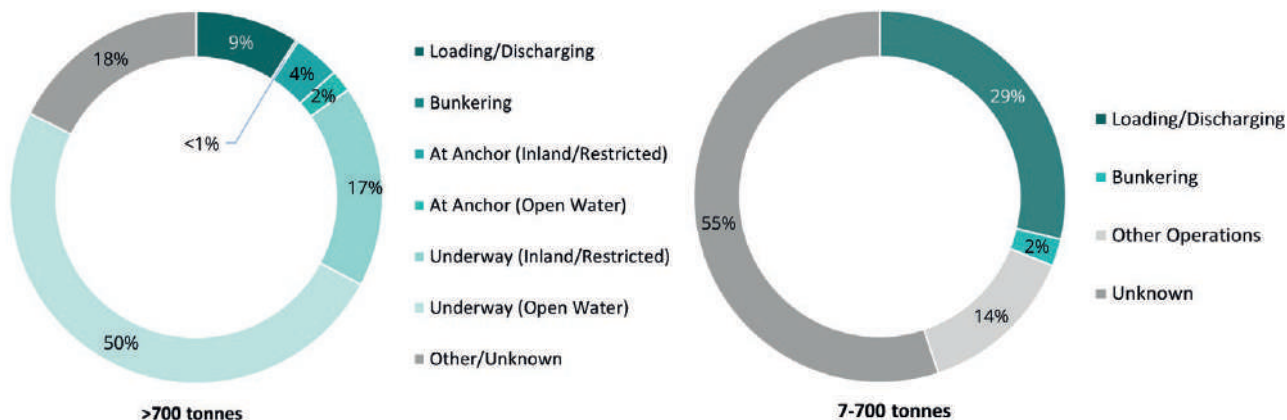

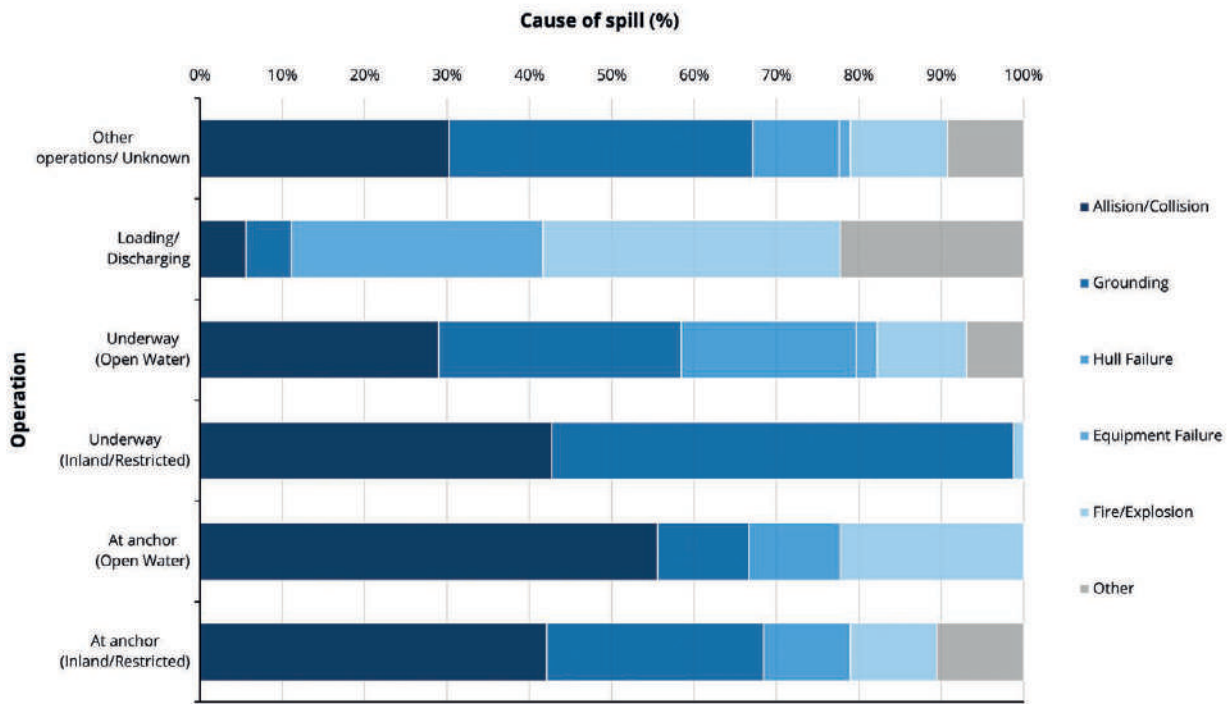

Figure 12: Number of tanker spills by operation at time of incident, 1970-2021

Although reporting of medium spills has improved over recent decades, information available from the 1970s is deficient. Vessel operations for medium spills have therefore been grouped into Loading/Discharging, Bunkering, Other Operations and Unknown Operations. Other Operations include activities such as ballasting, de-ballasting, tank cleaning and when the vessel is underway.

From Figure 12, it can be seen that 50% of large spills occurred while the vessels were underway in open water; allisions, collisions and groundings account for 58% of the causes of these spills (Figure 13). These same causes account for an even higher percentage of spills

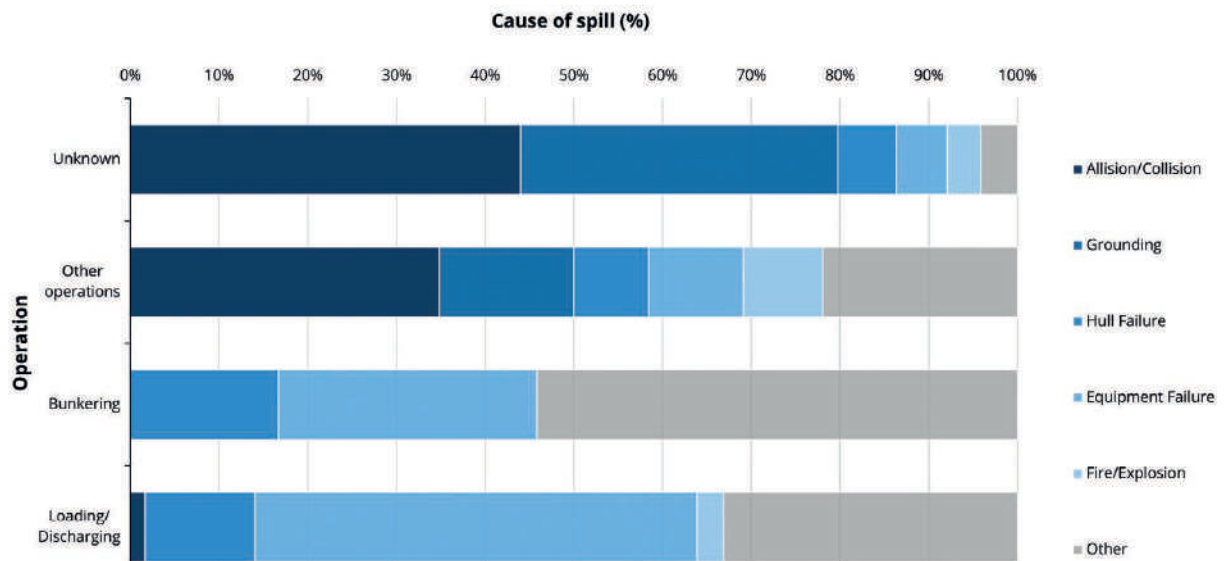

(99%) when the vessels were underway in inland or restricted waters. Restricted waters include water areas in ports and harbours.

Nine percent of large spills recorded occurred during loading or discharging activities (Figure 12) which normally take place in ports and oil terminals. Significantly more medium sized spills (29%) occurred during these operations. For large spills, 36% were caused by fires and explosions. In contrast, during loading and discharging, less than 5% of medium sized spills were caused by fires and explosions. In addition, 31% of large spills resulted from equipment failures compared to approximately 50% for medium spills (Figures 13 & 14).

\* Unknown causes are excluded

Figure 13: Number of tanker spills >700 tonnes by operation at time of incident and primary cause of spill, 1970-2021

\* Unknown causes are excluded

Figure 14: Number of tanker spills 7-700 tonnes by operation at time of incident and primary cause of spill, 1970-2021

Tables 4 and 5 show the number of spills by cause and operation for large and medium spills recorded from 1970 to 2021.

| Causes             | Operations                           |                              |                                     |                             |                         |                                 | Total      |

Table 5: Number of tanker spills 7-700 tonnes by operation at time of incident and primary cause of spill, 1970-2021

# Current Trends – Spills since 2010

The global oil tanker spill trend is firmly downward, however, when the frequency of spills since 2010 is reviewed (Figure 15), fluctuations in yearly values within a decade, illustrated in Figure 2, can be seen. As expected, these differences are not as vast as they are for some years in previous decades. As the number of spills recorded each year approaches zero, the

fluctuations are decreasing and the figures largely stabilising.

The annual average number of spills >7 tonnes for the 2010s was 6.3, which is a 65% drop from the average in the previous decade (Figure 2 & 15). The annual average so far this decade is 5.

Figure 15: Number of tanker spills and quantities of oil spilt (>7 tonnes) from 2010-2021

With regard to the volume of oil spilt during the last decade, low annual quantities compared to prior decades were recorded for most years. However, a single large spill in 2018 resulted in the largest annual quantity of oil spilt in 24 years being recorded (Figure 15). Also, the spill amount for 2021 is the second highest estimate in the last ten years.

The most frequent cause of medium and large spills since 2010 is Allisions/Collisions. About 40% of spills resulted from allisions or collisions, which is higher than the proportions recorded for most previous decades since 1970 (Figure 11). Groundings, conversely, have decreased significantly over the period. Ten percent of spills (>7 tonnes) recorded since 2010 were as a result of groundings compared to 30% for the 1970s (Figure 10).

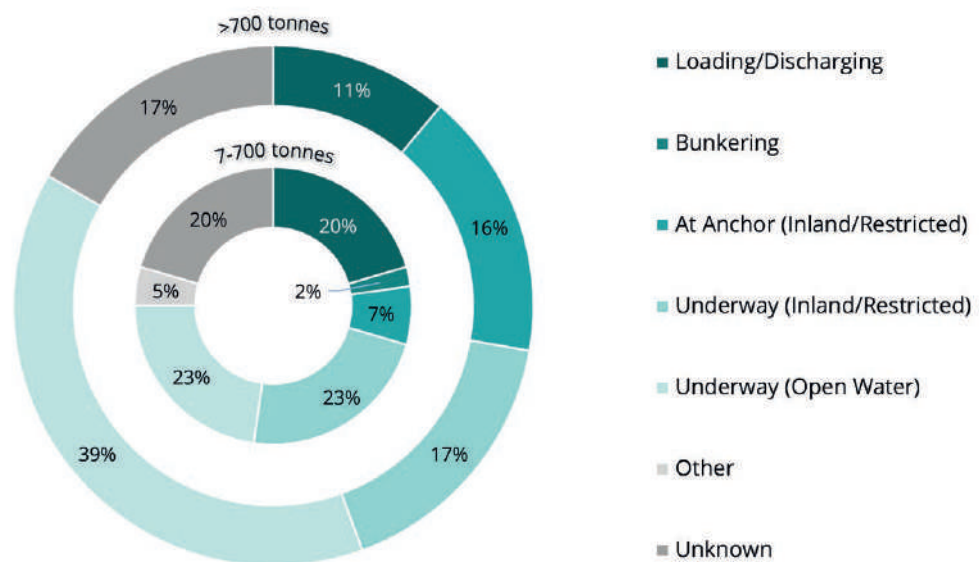

Figure 16: Causes of tanker spills, 2010-2021

Figure 12 shows that for data gathered on medium sized spills since 1970, operations that vessels were undertaking at the time of incident were largely unknown (over 50%). However, data since 2010 shows that reporting has improved and the proportion of medium spills attributable to ‘unknown’ causes has reduced to 20%, close to the 17% recorded for large spills. This suggests that more accurate and consistent information is becoming available for spills of less than 700 tonnes.

This has allowed further breakdown of vessel operations for medium spills as shown in Figure 17.

Similar to what was observed for earlier decades, most large spills since 2010 occurred while the vessels were underway in open water. For medium spills, the percentage of spills that occurred while the vessels were underway in inland water compared to open water (Figure 17) is equal.

\* None of the spills occurred while the vessel was “At Anchor in Open Water”

# About ITOPF

---

ITOPF is maintained by the world's shipowners and their insurers on a not-for-profit basis to promote effective response to spills of oil, chemicals and other substances in the marine environment.

Since ITOPF's establishment in 1968, our technical staff have attended on-site at over 800 shipping incidents in 100 countries to provide objective and scientific advice on clean-up measures, the effects of pollutants on the environment and economic activities, and on compensation. These incidents can involve oil, chemicals and other cargoes, whether bulk or packaged, as well as bunker fuel from all types of ship. We also provide advice in relation to oil spills from other potential sources of marine pollution, including pipelines and offshore installations; physical damage to coral reefs resulting from ship groundings; and environmental impacts associated with shipwrecks.

Our first-hand experience of pollution incidents is utilised during contingency planning and other advisory assignments for government and industry. We are an authoritative source of information on marine spills and share our knowledge at training courses and seminars throughout the world, encouraging best practice through outreach and education.

*Practical guidance on oil and chemical spill response and effects in the marine environment is available through ITOPF's Technical Information Papers (TIPs) and its Response to Marine Oil Spills film series.*

## ITOPF TIPs

- 1 Aerial Observation of Marine Oil Spills
- 2 Fate of Marine Oil Spills
- 3 Use of Booms in Oil Pollution Response
- 4 Use of Dispersants to Treat Oil Spills
- 5 Use of Skimmers in Oil Pollution Response
- 6 Recognition of Oil on Shorelines
- 7 Clean-up of Oil from Shorelines
- 8 Use of Sorbent Materials in Oil Spill Response
- 9 Disposal of Oil and Debris
- 10 Leadership, Command & Management of Oil Spills
- 11 Effects of Oil Pollution on Fisheries and Mariculture
- 12 Effects of Oil Pollution on Social and Economic Activities
- 13 Effects of Oil Pollution on the Environment
- 14 Sampling and Monitoring of Marine Oil Spills
- 15 Preparation and Submission of Claims from Oil Pollution
- 16 Contingency Planning for Marine Oil Spills
- 17 Response to Marine Chemical Incidents
- 18 Ship Groundings on Coral Reefs

## ITOPF Film Series

- 1 Introduction to Oil Spills
- 2 Aerial Surveillance
- 3 At-Sea Response
- 4 Shoreline Clean-up
- 5 Waste Management
- 6 Environmental Impacts
- 7 Oil Spill Compensation
- 8 Oil Spills in Cold Climates

The TIPs and films are available in multiple languages on ITOPF's website [www.itopf.org](http://www.itopf.org).
